1. We describe a simple model for these data. Let p $(0 < p < 1)$ denote the weekly failure probability, i.e., the probability of failure during any week, and T the random variable describing the week at which failure occurred. Then T may be modeled as a geometric random variable:

$$\mathbb{P}\left(T = t \mid p\right) = \begin{cases} p\left(1-p\right)^{t-1}, & t = 1, 2, \ldots; \\ 0, & \text{otherwise.} \end{cases} \tag{1}$$

Let Y_t represent the number of components that fail in week t, $t = 1, 2, \ldots, N$, and Y_{N+1} the number of components that have not failed by week N.

(a) Show that the likelihood function is

$$L\left(p\right) = \left[\left(1-p\right)^N\right]^{Y_{N+1}} \prod_{t=1}^{N} \left[p\left(1-p\right)^{t-1}\right]^{Y_t}. \tag{2}$$

Solution: An individual component's failure week has distribution Geometric (p). The probability that a single component fails in week t is the probability that it survived $t-1$ weeks and failed on week t, which is $p\left(1-p\right)^{t-1}$. There are Y_t such components, which gives us the factors for $t = 1, 2, \ldots, N$.
The probability that a component fails at a later date is

$$\left(1-p\right)^N \sum_{k=1}^{\infty} p\left(1-p\right)^{k-1} = \left(1-p\right)^N \frac{p}{1-\left(1-p\right)} = \left(1-p\right)^N,$$

which gives us the remaining factor. There are Y_{N+1} remaining components, so

$$L\left(p\right) = \left\{\prod_{t=1}^{N} \left[p\left(1-p\right)^{t-1}\right]^{Y_t}\right\} \times \left[\left(1-p\right)^N\right]^{Y_{N+1}}.$$
